Overview

Serial API allows external application or device to communicate with the SimpleBGC controller via UART port. Each controller has one or more UART ports that can be used to send and receive Serial API commands. Commands may be used to retrieve actual system state and realtime data, change settings, control gimbal, trigger pin state, execute various actions, get access to internal EEPROM and I2C bus, and so on. Moreover, SimpleBGC GUI software uses the same Serial API to communicate with the board, so all of its functions may be implemented in third-party applications.

Message format

Communications is initiated from the GUI side (host) by sending *outgoing* commands. The controller board may do some action and send response (further named as *incoming* commands). Each command consists of the *header* and the *body*, both with checksum. Commands with the wrong header or body checksum, or with the body size that differs from expected, should be ignored.

Board can work on different serial baud rate, so the GUI should find proper baud rate by sending CMD_BOARD_INFO command on every speed ant wait for response, until valid response is received.

32bit boards with firmware version 2.40, works only with parity=EVEN COM-port setting. Starting from 2.41, both EVEN and NONE parity are supported (NONE is default, and EVEN is detected automatically). So beside baud rates, host should vary parity setting when connecting to boards ver.>3.0

Make a small delay after sending each command to prevent overflow of the input buffer. Delay should be about 10-20 ms, and depends on the size of the request and response. If new serial data comes when the input buffer is full, whole message will be lost. There is also a control of overflow of the output buffer on the board's side: if it have to write an answer to the output buffer, it hangs until buffer will have enough space to accept new data. If requests comes with too big rate, it may negatively affect normal operation of the board and impact stabilization.

Input and output commands have the same format, described below:

Header:

```
character '>'
command ID - 1u
data_size - 1u, may be zero
header checksum = (command ID + data size) modulo 256 - 1u
```

Body:

```
[array of bytes data_size length] body checksum - 1u
```

Checksum is calculated as a sum of all bytes modulo 256.

Example: outgoing command to read Profile2:

0x3E (>)	0x52 (R)	0x01	0x53	0x01	0x01
	command id	data size	header checksum	data	body checksum
	hea	bo	dy		

Data type notation

• 1u – 1 byte unsigned

- 1s 1 byte signed
- 2u 2 byte unsigned (little-endian order)
- 2s 2 byte signed (little-endian order)
- 4f float (IEEE-754 standard)
- 4s 4 bytes signed (little-endian order)
- string ASCII character array, first byte is array size
- Nb byte array size N

CMD_CONTROL - Contro	l cam	era ang	le	
control_mode* extended format: control_mode_roll control_mode_pitc H control_mode_yaw	1u			Bits 03 for mode, bits 47 for flags. MODE_NO_CONTROL=0 If this mode is set for all axes, finish serial control and restore normal RC control. If set for single axis, does not change its current control mode. MODE_SPEED=1 Camera travels with the given speed in the Euler coordinates until the next CMD_CONTROL command comes. Given angle is ignored. MODE_ANGLE=2* Camera travels to the given point in the Euler coordinates with the given speed. MODE_SPEED_ANGLE=3 Camera travels with the given speed while the actual angle matches the given angle.

				Additionally, PID controller keeps the given angle. This mode allows the most precise and error-proof control. See fig.1 for example.
				MODE RC=4*
				Angle parameter is used as RC data and overrides any other signal source. Should be in range -500500. Prior to 2.61 frw.ver., 'SPEED' parameter is ignored.
				MODE_ANGLE_REL_FRAME=5* First, the neutral point of a camera relative to a frame is found in the Euler coordinates. Than, the given angle value is add to this point, and camera travels to it. For example, if the ANGLE parameter = 0 and camera made 2 full turns by YAW, it will make 2 turns back and returns to neutral point.
				CONTROL_FLAG_HIGH_RES_SPEED=(1<<7) Speed units changed to 0.001 deg/sec for extremely slow motion (timelapse shooting) (frw.ver 2.60+)
				* In the control modes "MODE_ANGLE", "MODE_RC", and "MODE_ANGLE_REL_FRAME", if the 'SPEED' parameter > 0, it is used instead of the default value defined by the RC settings. Relationship: SPEED = settings.RC_SPEED*16
SPEED_ROLL SPEED_PITCH	2s	-	-	Speed of rotation. If acceleration limiter is enabled in the settings, given speed may be limited.
SPEED_YAW				Units: 0,1220740379 degree/sec or 0.001 degree/sec, if CONTROL_FLAG_HIGH_RES_SPEED is set
ANGLE_ROLL ANGLE_PITCH ANGLE_YAW	2s	-32768	32767	Target angle. Ignored in the "MODE_SPEED" mode. If mode="MODE_RC", it specifies RC data in range -500500
				Units: 0,02197265625 degree.

Notes:

- Serial control overrides RC control. To switch back to RC, send this command with the mode=MODE_NO_CONTROL and all data set to zeros.
- Optimal rate of sending this command is 50..100Hz. If the rate of CMD_CONTROL command is lower, use a low-pass filtering to prevent step-wise response. It can be set by the command CMD_CONTROL_CONFIG.
- See <u>Appendix A</u> for source code example
